

A toric proof of Bézout's theorem for weighted projective spaces

Bernt Ivar Utstøl Nødland

April 11, 2016

Abstract

Using toric geometry we prove a Bézout type theorem for weighted projective spaces.

1 Introduction

The classical Bézout's Theorem for projective space states that for divisors D_1, \dots, D_n on \mathbb{P}^n we have $D_1 \cdots D_n = \prod_{i=1}^n \deg D_i$ [Ful98, Prop. 8.4]. Using toric geometry we will generalize this formula to weighted projective spaces $\mathbb{P}(q_0, \dots, q_n)$:

Theorem 1.1 (Bézout's Theorem). *Given n torus-invariant divisors E_1, \dots, E_n on $\mathbb{P}(q_0, \dots, q_n)$, we have*

$$E_1 \cdots E_n = \frac{\prod_{i=1}^n \deg E_i}{q_0 \cdots q_n}.$$

We recover Bézout's theorem for weighted homogeneous polynomials [EH99, Thm. 3.6] by choosing effective divisors intersecting in finitely many points with an additional hypothesis on the degrees of the polynomials defining the divisors. Our theorem also generalizes Bézout's theorem for the weighted projective plane given in [ABMMOG12, Prop. 5].

This paper is based on results from my master thesis [Nø15] and is written as part of my PhD thesis at the University of Oslo, supervised by Ragni Piene and John Christian Ottem.

2 Preliminaries on intersection theory and WPS

For any n -dimensional variety X let $Z_k(X)$ be the free abelian group generated by the set of irreducible closed subvarieties of dimension k on X . We define

rational equivalence: Let $\alpha \in Z_k(X)$ be equivalent to zero if there exist finitely many $(k+1)$ -dimensional subvarieties $V_i \subseteq X$ such that α is the divisor of a rational function on V_i for all i . Then the k -th Chow group $A_k(X)$ is $Z_k(X)$ modulo rational equivalence.

We use notation and definitions from [CLS11] for toric varieties. For a complex toric variety X_Σ defined by a fan Σ , $A_k(X_\Sigma)$ is generated by the classes of the orbit closures $\overline{O(\sigma)}$ of the cones $\sigma \in \Sigma(n-k)$ ([Ful93, Ch.5.1]). If Σ is complete and simplicial, setting $A^k(X_\Sigma) = A_{n-k}(X_\Sigma)$, one can define a product

$$A^k(X) \otimes \mathbb{Q} \times A^l(X) \otimes \mathbb{Q} \rightarrow A^{k+l}(X) \otimes \mathbb{Q}$$

which agrees with geometric intersection in nice cases (see [Dan78, Remark 10.9]). This makes the groups of cycles into a graded ring $A^\bullet(X_\Sigma)_\mathbb{Q}$.

To compute intersections we will also consider the Chow ring of a toric variety, as defined in [CLS11, Ch. 12.5].

Given a fan Σ , let $\Sigma(1) = \{\rho_1, \dots, \rho_r\}$. Denote by u_i the minimal generator of ρ_i . We will consider two ideals \mathcal{I}, \mathcal{J} in the polynomial ring $\mathbb{Q}[x_1, \dots, x_r]$. Let

$$\begin{aligned} \mathcal{I} &= \langle x_{i_1} \cdots x_{i_s} \mid \text{all } i_j \text{ distinct and } \rho_{i_1} + \cdots + \rho_{i_s} \text{ is not a cone in } \Sigma \rangle, \\ \mathcal{J} &= \left\langle \sum_{i=1}^r \langle m, u_i \rangle x_i \mid \text{where } m \text{ ranges over a basis of } M \right\rangle. \end{aligned}$$

The ideal \mathcal{I} is called the Stanley–Reisner ideal. The Chow ring $R_\mathbb{Q}(\Sigma)$ is defined as

$$R_\mathbb{Q}(\Sigma) = \mathbb{Q}[x_1, \dots, x_r] / \mathcal{I} + \mathcal{J}.$$

We have that if X_Σ is complete and simplicial, then by [CLS11, Thm 12.5.3]

$$R_\mathbb{Q}(\Sigma) \cong A^\bullet(X_\Sigma)_\mathbb{Q}.$$

We have from [CLS11, Example 3.1.17] the fan for a weighted projective space: Given natural numbers q_0, \dots, q_n with $\gcd(q_0, \dots, q_n) = 1$, consider the quotient lattice of \mathbb{Z}^{n+1} by the subgroup generated by (q_0, \dots, q_n) . We write $N = \mathbb{Z}^{n+1} / \mathbb{Z}(q_0, \dots, q_n)$. Let u_i for $i = 0, \dots, n$ be the images in N of the standard basis vectors of \mathbb{Z}^{n+1} . This means that in N we have the relation

$$q_0 u_0 + \dots + q_n u_n = 0.$$

Let Σ be the fan consisting of all cones generated by proper subsets of $\{u_0, \dots, u_n\}$. Then $X_\Sigma = \mathbb{P}(q_0, \dots, q_n)$, which is complete and simplicial. Moreover, we have

$$\mathcal{I} = \langle x_0 \cdots x_n \rangle.$$

Since we are over \mathbb{Q} , a basis for $M \otimes \mathbb{Q} = \{m \in \mathbb{Z}^{n+1} \mid \sum q_i m_i = 0\}$ will be $(q_i, 0, \dots, 0, -q_0, 0, \dots, 0)$, for $i = 1, \dots, n$. This gives the ideal

$$\mathcal{J} = \langle q_i x_0 - q_0 x_i \mid i = 1, \dots, n \rangle.$$

Doing the computations, we can eliminate x_1, \dots, x_n since $x_i = \frac{q_i}{q_0} x_0$, so the Chow ring will be

$$R_\mathbb{Q}(\Sigma) \cong \mathbb{Q}[x_0] / x_0^{n+1}.$$

The group of torus-invariant divisors is the free abelian group generated by one prime divisor D_i for each 1-dimensional ray ρ_i in Σ . The 1-graded part of $R_{\mathbb{Q}}(\Sigma)$ corresponds to $\text{Cl}(\mathbb{P}(q_0, \dots, q_n)) \otimes \mathbb{Q}$. It is well known that $\text{Cl}(\mathbb{P}(q_0, \dots, q_n))$ is isomorphic to \mathbb{Z} via the degree map, where $\deg D_i = q_i$ (see for instance [RT11, Thm. 1.19]). Then we have relations $q_i D_0 = q_0 D_i$, thus choosing the image of D_0 (by abuse of notation we denote this by D_0 as well) as a generator for $\text{Cl}(\mathbb{P}(q_0, \dots, q_n)) \otimes \mathbb{Q} \simeq \mathbb{Q}$, we get that D_i is mapped to $\frac{q_i}{q_0} D_0$. Taking any torus-invariant divisor $D = \sum_{i=0}^n a_i D_i$, we have $\deg D = \sum_{i=0}^n a_i q_i$. Then in the Chow ring, D gets mapped to $\sum_{i=0}^n a_i D_i = \sum_{i=0}^n a_i \frac{q_i}{q_0} D_0 = \frac{D_0}{q_0} \sum_{i=0}^n a_i q_i = \frac{\deg D}{q_0} D_0$.

Taking n torus-invariant divisors E_1, \dots, E_n it then follows

$$E_1 \cdots E_n = \frac{\prod_{j=1}^n \deg E_j}{q_0^n} D_0^n,$$

thus we have determined intersections of divisors modulo the generator D_0^n . We wish to push this forward to $\text{Spec } \mathbb{C}$ to obtain an actual number, i.e., to calculate $\int_{X_{\Sigma}} D_0^n$.

If a complete variety X_{Σ} of dimension n is embedded in \mathbb{P}^s via a very ample divisor D , define $D^n := \deg(X_{\Sigma} \subset \mathbb{P}^s) = \int_{X_{\Sigma}} D^n$. Then by [CLS11, Thm. 13.4.3], D^n equals $\text{Vol}(P_D)$, i.e., the volume of the polytope associated to the divisor, normalized with respect to the lattice M .

To apply this we need to describe a polytope giving $\mathbb{P}(q_0, \dots, q_n)$. From [RT11, Remark 1.24 and Cor 1.25] we have the following polytope:

Given (q_0, \dots, q_n) and $M \cong \mathbb{Z}^{n+1}$, let $\delta = \text{lcm}(q_0, \dots, q_n)$. Consider the $n+1$ points of $M_{\mathbb{R}} \cong \mathbb{R}^{n+1}$:

$$v_i = (0, \dots, \frac{\delta}{q_i}, \dots, 0)$$

Let Δ be the convex hull of 0 and all v_i . Intersecting Δ with the hyperplane $H = \{(x_0, \dots, x_n) \mid \sum_{i=0}^n x_i q_i = \delta\}$, we get an n -dimensional polytope P . Then $X_P \cong \mathbb{P}(q_0, \dots, q_n)$ and the divisor D associated to the polytope will be $\frac{\delta}{q_0} D_0$ which is very ample.

If we can determine the volume of P , we can determine D_0^n , since

$$\text{Vol}(P) = D^n = \frac{\delta^n}{q_0^n} D_0^n,$$

implying that $D_0^n = \text{Vol}(P) \frac{q_0^n}{\delta^n}$.

3 Proof of Theorem 1.1

To determine the volume of P , we will use the generalized cross product (see [Mas83]). For n vectors $v_1, \dots, v_n \in \mathbb{R}^{n+1}$, let A be the matrix with i -th row v_i . The cross product $v_1 \times \cdots \times v_n \in \mathbb{R}^{n+1}$ has k -th coordinate equal to $(-1)^k$ times the $n \times n$ minor of A obtained by removing the k -th column. This cross

product is orthogonal to all v_i and satisfies

$$|v_1 \times \cdots \times v_n| = \text{Vol}(v_1, \dots, v_n),$$

where $\text{Vol}(v_1, \dots, v_n)$ is the n -dimensional volume of the parallelotope spanned by v_1, \dots, v_n (this product can be expressed by exterior algebra operations as the Hodge dual $*(v_1 \wedge \cdots \wedge v_n)$).

To determine the volume, we first need to normalize with respect to the lattice, i.e., we need to determine the volume spanned by a basis. We will need the following to choose a basis for the lattice spanned by P : Given set of linearly independent vectors $b_1, \dots, b_n \in M$ let

$$T(b_1, \dots, b_n) = \left\{ \sum_{i=1}^n c_i b_i \mid 0 \leq c_i < 1 \right\} \subseteq M_{\mathbb{R}} = M \otimes \mathbb{R}.$$

The following is well-known, but we include a proof for lack of a proper reference:

Lemma 3.1. *The vectors b_1, \dots, b_n form a basis for the lattice M if and only if $T(b_1, \dots, b_n) \cap M = \{0\}$.*

Proof. Assume (b_1, \dots, b_n) is a basis. Let $x \in T(b_1, \dots, b_n) \cap M$. Then $x = \sum_{i=1}^n c_i b_i = \sum_{i=1}^n n_i b_i$ for $0 \leq c_i < 1$, $n_i \in \mathbb{Z}$. Thus $0 = \sum_{i=1}^n (c_i - n_i) b_i$. Since the b_i 's are linearly independent, this implies that $c_i = n_i$, hence $c_i = 0$.

Assume $T(b_1, \dots, b_n) \cap M = \{0\}$. Pick a lattice point $x \in M$. Since b_1, \dots, b_n is a basis for the vector space $M_{\mathbb{R}}$ we can find $d_i \in \mathbb{R}$ such that $x = \sum_{i=1}^n d_i b_i$. Let $d_i = n_i + c_i$ where $n_i \in \mathbb{Z}$ and $0 \leq c_i < 1$. Then $x - \sum_{i=1}^n n_i b_i \in T(b_1, \dots, b_n) \cap M = \{0\}$, hence $c_i = 0$ for all i . Thus b_1, \dots, b_n is a basis for M . \square

First we choose an edge of the polytope P , say the edge $v_0 v_1$, which is generated by $(-\frac{\delta}{q_0}, \frac{\delta}{q_1}, 0, \dots, 0)$. For simpler notation set $q_{i_1, \dots, i_s} = \text{gcd}(q_{i_1}, \dots, q_{i_s})$. The primitive generator of the edge $v_0 v_1$ will be $e_1 = (-\frac{q_1}{q_{01}}, \frac{q_0}{q_{01}}, 0, \dots, 0)$. Now, choose any lattice point of $H = \{(x_0, \dots, x_n) \mid \sum_{i=0}^n x_i q_i = \delta\}$ of the form

$$(x_{20}, x_{21}, \frac{q_{01}}{q_{012}}, 0, \dots, 0),$$

this exists since the numbers obtained as integral linear combination of q_0, q_1 are exactly all multiples of q_{01} , and $\delta - q_2 \frac{q_{01}}{q_{012}}$ is such a multiple (the subscripts are chosen for notational purposes which will become clear). Set e_2 as the difference between this point and v_0 , in other words

$$e_2 = (x_{20} - \frac{\delta}{q_0}, x_{21}, \frac{q_{01}}{q_{012}}, 0, \dots, 0).$$

In general, for all $2 \leq s \leq n$ find a lattice point of the form

$$(x_{i_0}, x_{i_1}, \dots, x_{i_{(s-1)}}), \frac{q_{0 \dots s-1}}{q_{0 \dots s}}, 0, \dots, 0).$$

This is equivalent to saying

$$x_{i_0}q_0 + x_{i_1}q_1 + \cdots + x_{i_{(s-1)}}q_{s-1} + \frac{q_{0\dots s-1}}{q_{0\dots s}}q_s = \delta.$$

Set

$$e_s = \left(x_{i_0} - \frac{\delta}{q_0}, x_{i_1}, \dots, x_{i_{(s-1)}}, \frac{q_{0\dots s-1}}{q_{0\dots s}}, 0, \dots, 0\right).$$

Then we have

Proposition 3.2. *The n vectors $\{e_1, \dots, e_n\}$ constructed above, are a basis for the lattice spanned by H .*

Proof. We will use Lemma 3.1 to show this. Assume we have a lattice point $l = \sum_{i=1}^n c_i e_i$, where $0 \leq c_i < 1$ for all i . Then it suffices to show that all $c_i = 0$. We will show this by descending induction on c_n . Let $l = (y_0, \dots, y_n)$. Then we have, by definition of H ,

$$\sum_{i=0}^n q_i y_i = \delta. \quad (1)$$

Consider the $(n+1)$ -th coordinate. Since the basis is constructed in such a way that the only vector having nonzero $(n+1)$ -th coordinate is e_n , we must have $y_n = c_n \frac{q_{0\dots n-1}}{q_{0\dots n}}$. When we defined weighted projective space, we assumed $q_{0\dots n} = 1$. Thus we must have $y_n = c_n q_{0\dots n-1}$. Now consider (1) modulo $(q_{0\dots n-1})$: The righthand side is 0 and the first terms $q_0 y_0 + \dots + q_{n-1} y_{n-1}$ will be zero, since in general integral linear combinations of a set of integers are exactly the multiples of their greatest common divisor. Thus we must have

$$q_n y_n \equiv q_n c_n q_{0\dots n-1} \equiv 0 \pmod{q_{0\dots n-1}}.$$

Now since $c_n < 1$, we have $c_n q_{0\dots n-1} < q_{0\dots n-1}$, and if $0 < c_n$ there must be some prime power p^r dividing $q_{0\dots n-1}$ which does not appear in $c_n q_{0\dots n-1}$. But then we must have that p divides q_n , which implies $q_{0\dots n} > 1$ which is a contradiction. Thus $c_n = 0$.

Assume in general we have proved that $c_n = c_{n-1} = \dots = c_{s+1} = 0$. We will show that $c_s = 0$. We will use the same method as above: Since $c_{s+1} = \dots = c_n = 0$, we have a linear combination $l = \sum_{i=0}^s c_i e_i$. In the set $\{e_1, \dots, e_s\}$, the only vector with $(s+1)$ -th coordinate nonzero will be e_s . Thus we must have $y_s = c_s \frac{q_{0\dots s-1}}{q_{0\dots s}}$. Considering (1) modulo $q_{0\dots s-1}$ we get

$$q_s y_s \equiv q_s c_s \frac{q_{0\dots s-1}}{q_{0\dots s}} \equiv 0 \pmod{q_{0\dots s-1}}.$$

Now, since l is a lattice point, $c_s \frac{q_{0\dots s-1}}{q_{0\dots s}}$ is an integer $k < \frac{q_{0\dots s-1}}{q_{0\dots s}}$. Rewriting the above we get

$$\frac{q_s}{q_{0\dots s}} k q_{0\dots s} \equiv 0 \pmod{q_{0\dots s-1}}, \quad (2)$$

since $k q_{0\dots s} = c_s q_{0\dots s-1} < q_{0\dots s-1}$, we must have, if $0 < c_s$, that there is a prime power p^r in the prime factorization of $q_{0\dots s-1}$, which appears to a smaller degree in the prime factorization of $c_s q_{0\dots s-1}$. By the previous equality, the

highest power of p which can appear in $q_{0,\dots,s}$ will also be smaller than r , say it is $(r-t)$. But to satisfy (2) we must also have that p divides $\frac{q_s}{q_{0,\dots,s}}$, which implies that p^{r-t+1} divides q_s , but then p^{r-t+1} will divide $q_{0,\dots,s}$ which is a contradiction. Thus we must have $c_s = 0$.

The last case is an exception. If $s = 0$ we have $l = c_0 e_0$, but by construction of e_0 as a primitive vector we must have $c_0 = 0$. Hence we are done. \square

Now we can use this to calculate the normalized volume.

Proposition 3.3. *The volume of the parallelotope spanned by e_1, \dots, e_n is $\sqrt{q_0^2 + \dots + q_n^2}$.*

Proof. The coordinates of $z = e_1 \times \dots \times e_n$ will be (modulo a sign) the $n \times n$ minors of the matrix A with row i equal to e_i .

$$A = \begin{bmatrix} -\frac{q_1}{q_{01}} & \frac{q_0}{q_{01}} & 0 & 0 & \dots & 0 \\ x_{20} - \frac{\delta}{q_0} & x_{21} & \frac{q_{01}}{q_{012}} & 0 & \dots & 0 \\ x_{30} - \frac{\delta}{q_0} & x_{31} & x_{32} & \frac{q_{012}}{q_{0123}} & \ddots & 0 \\ \vdots & \vdots & \vdots & \ddots & \ddots & 0 \\ x_{n0} - \frac{\delta}{q_0} & x_{n1} & x_{n2} & x_{n3} & \dots & \frac{q_{0,\dots,n-1}}{q_{0,\dots,n}} \end{bmatrix}$$

Set $z = (z_0, \dots, z_n)$. We see immediately that $z_0 = q_0$ and $z_1 = q_1$, since the corresponding minors are lower triangular and $q_{0,\dots,n} = 1$. To calculate z_s we get, by expanding along the columns from the right, that $z_s = (-1)^s q_{0,\dots,s} \det(B_s)$ where B_s is the $s \times s$ submatrix from the upper left corner of A . Consider such a B_s :

$$B_s = \begin{bmatrix} -\frac{q_1}{q_{01}} & \frac{q_0}{q_{01}} & 0 & 0 & \dots & 0 \\ x_{20} - \frac{\delta}{q_0} & x_{21} & \frac{q_{01}}{q_{012}} & 0 & \dots & 0 \\ x_{30} - \frac{\delta}{q_0} & x_{31} & x_{32} & \frac{q_{012}}{q_{0123}} & \ddots & 0 \\ \vdots & \vdots & \vdots & \ddots & \ddots & 0 \\ \vdots & \vdots & \vdots & \ddots & \ddots & \frac{q_{0,\dots,s-2}}{q_{0,\dots,s-1}} \\ x_{s0} - \frac{\delta}{q_0} & x_{s1} & x_{s2} & x_{s3} & \dots & x_{s(s-1)} \end{bmatrix}$$

Enumerating the columns $0, \dots, s-1$, after multiplying column i by q_i (thus changing the determinant by a factor of $q_0 \cdots q_{s-1}$) for all i , observe that, by the construction of e_i , the sum of all rows except the last one is 0. For $i = 0, \dots, s-2$ do successively the column operation: add column i to column $i+1$. This will not change the determinant, and observe that by the remark about the row sums, the new matrix will be lower triangular. Thus the determinant will be the product of the diagonal elements.

Diagonal entry number r will be equal to $x_{r0}q_0 - \delta + x_{r1}q_1 + \dots + x_{r(r-1)}q_{r-1}$, which by construction equals $-\frac{q_0 \dots q_{r-1}}{q_0 \dots r}$. So we get

$$\frac{1}{q_0 \dots q_{s-1}} \det(B_s) = (-1)^s \frac{q_0 \dots q_s}{q_0 \dots s}$$

implying that $z_s = q_s$.

The result now follows from the fact that $|z|^2 = q_0^2 + \dots + q_n^2$. □

By this result, we have that a polytope with a Euclidean volume of $\frac{\sqrt{q_0^2 + \dots + q_n^2}}{n!}$ will have normalized lattice volume equal to 1, in the lattice spanned by H . Using this we have:

Proposition 3.4. *The normalized volume of P is $\frac{\delta^n}{q_0 \dots q_n}$.*

Proof. The edges emanating from v_0 are spanned by the vectors

$$w_i = \left(-\frac{\delta}{q_0}, 0, \dots, \frac{\delta}{q_i}, 0, \dots, 0\right),$$

for $i = 1, \dots, n$. The Euclidean volume of P will be $\frac{|w_1 \times \dots \times w_n|}{n!}$. The corresponding matrix is

$$\begin{bmatrix} -\frac{\delta}{q_0} & \frac{\delta}{q_1} & 0 & 0 & \dots & 0 \\ -\frac{\delta}{q_0} & 0 & \frac{\delta}{q_2} & 0 & \dots & 0 \\ -\frac{\delta}{q_0} & 0 & 0 & \frac{\delta}{q_3} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \ddots & 0 \\ -\frac{\delta}{q_0} & 0 & 0 & 0 & \dots & \frac{\delta}{q_n} \end{bmatrix}.$$

We see that $w_1 \times \dots \times w_n = \left(\frac{\delta^n}{q_1 \dots q_n}, \frac{\delta^n}{q_0 q_2 \dots q_n}, \dots, \frac{\delta^n}{q_0 \dots q_{i-1} q_{i+1} \dots q_n}, \dots, \frac{\delta^n}{q_0 \dots q_{n-1}}\right)$. This implies

$$|w_1 \times \dots \times w_n|^2 = \frac{\delta^{2n} q_0^2 + \delta^{2n} q_1^2 + \dots + \delta^{2n} q_n^2}{q_0^2 \dots q_n^2},$$

giving

$$|w_1 \times \dots \times w_n| = \frac{\delta^n}{q_0 \dots q_n} \sqrt{q_0^2 + \dots + q_n^2}.$$

Combining this with the normalization yields the result. □

Finally we can return to intersection theory on $\mathbb{P}(q_0, \dots, q_n)$. Recall that we have $D_0^n = \text{Vol}(P) \frac{q_0^n}{\delta^n}$. Inserting the above gives $D_0^n = \frac{q_0^n}{q_0 \dots q_n}$. Combining this with the previous calculations we get

$$E_1 \dots E_n = \frac{\prod_{j=1}^n \deg E_j}{q_0^n} D_0^n = \frac{\prod_{j=1}^n \deg E_j}{q_0^n} \frac{q_0^n}{q_0 \dots q_n} = \frac{\prod_{j=1}^n \deg E_j}{q_0 \dots q_n}$$

thus we are done.
